Chromium sugar disorders: micronutrients. In the typical American diet, high in refined and processed foods, individuals with blood sugar disorders may have a special dietary need for higher amounts of one or more micronutrients.

Glucose homeostasis also depends on the presence of a wide range of micronutrients. In the typical American diet, high in refined and processed foods, many of these micronutrients are in short supply. In addition, some individuals with blood sugar disorders may have a special dietary need for higher amounts of one or more micronutrients.

The following nutrients are particularly important when considering blood sugar disorders:

**Chromium**

The effect of chromium on glucose metabolism apparently requires its conversion to glucose tolerance factor (GTF), a low-molecular-weight compound that contains chromium, niacin (nicotinic acid), glycine, glutamic acid, and cysteine. GTF has been shown to potentiate the action of insulin at the cellular level.1,4

Tissue chromium levels were found to decline with age in Americans.2 In other studies, including one by the U.S. Department of Agriculture, more than 50% of people consumed less than the lower level of chromium recommended by the National Academy of Sciences, Nutritional Research Council.3, 4 Chromium aspartate is a well-utilized form of supplemental chromium being solubilized at a wide range of pH. The amounts of chromium used in most clinical trials (150 to 200 ug/day) are apparently inadequate for some patients, even when more efficient chromium compounds are used. Larger amounts of chromium, such as 500 to 1,000 ug/day, have often had a greater benefit.5

**Niacin and Niacinamide**

As a component of glucose tolerance factor, niacin plays an important role in carbohydrate metabolism. Many refined foods consumed by Americans are depleted of niacin. Grains and other foods that are “enriched” usually contain added niacinamide, which apparently cannot be converted by the human body into niacin. In addition, many vitamin supplements contain niacinamide, rather than niacin. Although niacinamide is capable of performing most of the functions of vitamin B3, a small amount of niacin seems to be necessary for the synthesis of GTF. Both niacin and niacinamide may also be important for blood sugar control through a mechanism unrelated to GTF. As precurors to NAD, which is an important metabolite concerned with intracellular energy production, niacin and niacinamide may prevent the depletion of NAD in pancreatic B cells.

**Biotin**

The initial step in glucose utilization by the cell is its phosphorylation, mediated by the biotin-dependent enzyme hepatic glucokinase. Thus adequate biotin intake is required to initiate intracellular glucose into the cell.4

Biotin may also play a role in stabilizing blood sugar levels through biotin-dependent enzymes acetyl-CoA carboxylase and pyruvate carboxylase.3, 5 Thus biotin deficiency should be avoided in those with blood sugar disorders.

**Pyridoxine (vitamin B6)**

Serum vitamin B6 levels were below normal in 25% of 518 diabetics.7 Particularly where peripheral neuropathy is present, the inadequate B6 intake should be contemplated.8

**Copper**

Because the typical American diet contains only about half of the RDA (2mg/day) for copper9, 10, deficiency of this mineral may be common. Copper is involved with insulin binding, and copper deficiency in mammals may be reflected in increased glucosylated hemoglobin, indicative of chronically raised blood sugar levels.10

**Magnesium**

The American diet is often low in magnesium. Dietary surveys have shown that 80-85% of American women consume less than the RDA for the mineral.11 Daily magnesium intake in two other studies was only about two-thirds of the RDA.12, 13, 14 This may be particularly relevant in diabetics, where magnesium deficiency is thought to play a role in the development of insulin resistance.11 Serum magnesium has been found to be significantly lower in many diabetics1, 11; therefore, it is reasonable to make sure that diabetics have adequate dietary intake of magnesium. Low magnesium levels may also be associated with hypoglycemia.11

**Zinc**

Zinc is involved both with insulin synthesis by pancreatic B cells17 and insulin binding to liver and adipose tissue cells.18 People with zinc deficiency may have significantly higher glucose levels and lower insulin levels than similar patients without zinc deficiency.19

**Vitamin C (ascorbic acid)**

Ascorbic acid levels may be lower in diabetics than controls22 and patients with inadequate ascorbic acid levels may be found to have abnormal blood sugar curves.23 In addition, ascorbic acid may compete with glucose for transport across cell membranes,24 so that in hyperglycemia, ascorbic acid transport into the cell may be inhibited.25

Ascorbic acid deficiency may allow sorbitol to accumulate in erythrocytes, which may pre-dispose diabetics to certain types of end-organ damage.24 Care should be taken to ensure that those with blood sugar abnormalities have adequate ascorbic acid intake.

Manganese

Manganese is a cofactor for certain enzymes involved in the intermediary metabolism of carbohydrates. In addition, the concentration of manganese in the pancreas is approximately ten times higher than in other organs.37 The optimal intake of manganese is not known but at least half of the manganese is lost when whole grains are replaced by refined flour.38 The American diet may be low in manganese.44

Both B12 and folate are involved in a number of different steps in carbohydrate metabolism and the incidence of B12 deficiency was significantly greater in a series of diabetics than in the general population.31 Deficiency was associated with increased complications associated with diabetes. As many as 10% of diabetics may be vitamin B12 deficient.45 Care should be taken to ensure that thiamin intake is adequate in those with diabetes and hypoglycemia.32

Thiamin is necessary for energy metabolism in the liver and small intestine.31 Deficiency of thiamin is undesirable in those with blood sugar abnormalities.

Vitamin B1 (thiamin)

Central to carbohydrate metabolism and Krebs Cycle function is adequate thiamin levels, and diabetics are more often deficient in thiamin.32 Care should be taken to ensure that thiamin intake is adequate in those with diabetes and hypoglycemia.

Carnitine

Carnitine is involved as part of a vital transport mechanism of fat metabolism in which fat enters energy production pathway. Carnitine supplementation may be considered in those with blood sugar abnormalities.

Vanadium

Vanadate is an oxidized form of vanadium. Due to possible insulinotropic effects of vanadate,34 inadequate amounts of this trace mineral is undesirable in those with blood sugar abnormalities.

Vitamin E and Selenium

Vitamin E and selenium are essential nutritional factors which act as antioxidants and may be involved in glucose balance.35 As many complications associated with diabetes may be related to excess free radical activity, prudence demands that adequate selenium and vitamin E be supplied in the diabetic diet.

Product Information

Product #1850 available in 90 capsule bottles.

Product #1851 available in 180 capsule bottles.

Recommendation: Two (2) to six (6) capsules each day with meals as a dietary supplement or as otherwise directed by your healthcare professional.

Warning: If you are taking Diabetes medication, do not use this product without medical supervision.
